SPICA Spectroscopic sensitivity

Unique to SPICA

Unparalleled
sensitivity for

$\lambda > 20 \mu\text{m}$

particularly for
diffuse emission

For $\lambda > 30 \mu\text{m}$

high sensitivity
spectroscopy has
never been carried
out

A General View of Dust Formation, Processing, & Destruction in the ISM

SPICA
Space Based InfraRed Telescope for Cosmology and Astrophysics

Dust processing in a galactic scale is important for material evolution in the Universe

SNe important both for dust formation & destruction

Metal supply rate: SNe > AGB stars

Destruction rate by SN shocks

> Supply rate from stellar sources

-> most interstellar dust is formed in dense clouds

Issues

1. Dust formation efficiency and species formed in SNe
2. Destruction and processing in SN shocks and ISM
3. Dust formation in interstellar clouds

1. Dust formation in SNe

Major dust source in the early universe

$0.1 - 1 M_{\odot}$ per SN is required and theoretically predicted

But

Only a few SNe show evidence of dust formation
& they are all less than $0.1 M_{\odot}$

Much smaller than theoretical predictions

SN1987A $7.5 \times 10^{-4} M_{\odot}$ (Ercolano et al. 2007)

SN2003gd $0.02 M_{\odot}$ (Sugerman et al. 2006)

$4 \times 10^{-5} M_{\odot}$ (Meikle et al. 2007)

Multi-component nature of IR emission from SNe

Emission from formed dust & circumstellar dust
A wide spectral coverage ($>10\mu\text{m}$) is important

Sakon et al. (2009)

Again only $<10^{-4}M_{\odot}$ dust (carbon grains) detected for SN2006jc

MIR spectroscopy and chemical process in ejecta

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

SN 2004dj (Kotak et al. 2005)

Formation of CO reduces the condensate mass (cf. CO may not be stable in SNe? (Clayton et al. 1999, 2001))

^{58}Ni mass can be derived from [NiII]6.64 μm line to constrain SN models independently on gas T

MIR spectroscopy (4 - 20 μm) is important for the study of dust formation in SNe
 $R > 500$ is required to separate [FeII]26.0 μm from [OIV]25.9 μm

Silicate dust formation in SN2004et

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

(Kotak et al. 2009)

First detection of SiO (& its decrease)

& silicate dust at 10 μm feature

Detected dust mass is still small ($<10^{-4}M_{\odot}$)

FIR observations important to estimate warm/cool dust

4. Supernova remnants

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

Dunne et al. (2003)

Synchrotron subtracted
850μm image

Detection of cold dust of 2-4M_⊙ in Cas A

No cold dust in Cas A

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

AKARI/FIS
90μm

Spitzer/250μm
70μm

AKARI/FIS
160μm

AKARI/FIS
140μm

Koo, Sibthorpe, Moon, Martin et al.

AKARI 65 micron

Chandra X-ray

Warm dust (@ 65μm) is associated with SNR, but cold dust is foreground
SNR dust mass $< 0.1 M_{\odot}$

MIR spectroscopy of SNR: Dust

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

Composition of dust grains formed in ejecta still unknown

Only a few SNRs show IR emission from dust in ejecta

SNR G292.0+1.8

7, 15, 24 μ m color

15/24 μ m ratio

Chandra

Park et al. 2002

IR emission from the SN ejecta is clearly detected
($M_{\text{dust}} < 10^{-4} M_{\odot}$) together with emission from CSM

Dust feature in SNRs

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

IR spectra of dust in ejecta are available for a handful of SNRs

Features around 20-23 μm may be common for ejecta dust
A similar feature also seen in massive star-forming regions

A bit more SNR spectra

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

Ghavamian et al. 2009

Spatially resolved spectra
from MIR to FIR are important
to separate components

SPICA Observations of SNe & SNRs

A detailed 3D rendering of the SPICA (Space Infrared Telescope for Cosmic Age Studies) satellite. The satellite is shown from a perspective view, highlighting its complex structure, including the large sunshield, the main telescope body, and various instruments. It is set against a dark, starry background with a nebula-like glow in shades of red and orange.

Monitoring observations of nearby ($<25\text{Mpc}$) SNe to investigate the dust formation and chemistry in ejecta

High spatial & spectral resolution observations of (~ 50) SNRs in the Galaxy and galaxies that show IR emission to study the nature of dust formed in SN ejecta

A wide spectral coverage (4 - $200\mu\text{m}$) in a medium spectral resolution with sufficient spatial resolution is a key combination to investigate the contribution of each component and line emission

High spectral resolution in 4 - $8\mu\text{m}$ is important for the study of chemistry (CO & SiO)

High spatial resolution in FIR is crucial for the study of SNRs in external galaxies

2. AGB stars and PNe

Low- to intermediate-mass evolved stars are an important dust source in the ISM

Dust formation process there are an excellent natural laboratory for dust formation in the Universe
Interplay of the dynamics of the atmosphere and dust formation is important for mass-loss

1. Chemistry and dynamics of MOLsphere and its role in the formation of dust grains
2. Mass loss history and mechanism of AGB stars
3. Carbonaceous dust/PAH formation and processing in AGB and PNe

MOLsphere

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

MOLsphere detected in red giants by ISO spectroscopy
but no significant progress since ISO
A key region for dust formation and mass-loss

Chemistry in MOLsphere

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

Justtanont et al. 1998

High spectral resolution ($R \sim 30000$)
in 4 - 20 μm is important to
understand detailed chemistry and
dynamics in MOLsphere

Yamamura et al. 1999

Mass loss history

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

U Hya @AKARI 90 μ m

Izumiura et al.

100"

FIR imaging of multi-band with high sensitivity and high spatial resolution enables detailed study of mass-loss history and chemical evolution (e.g. $C/O < 1$ to $C/O > 1$) in the circumstellar dust shell

BD+303639@COMICS

Matsumoto et al. 2008

1"

High spatial resolution MIR spectroscopy indicates silicate dust around C-rich object

SPICA Observations of AGB and PNe

High spatial resolution observations of ~30 AGB stars and PNe in MIR to FIR to study mass-loss history, dust formation, and chemical evolution of the CSM

Search for weak UIR bands in C-stars to investigate the origin of the band carriers and the processing in the ISM

Origin of carbonaceous grains is important for the study of dust in the early Universe

High spatial resolution and high sensitivity for diffuse emission from MIR to FIR are a key for this study

High spectral resolution capability in MIR (4-20 μ m) is important for the study of gas in MOLsphere

3. Search for dust formed in the ISM

Theoretical studies indicate:

(i) stellar dust sources (SNe, AGB stars, ..)
replenish interstellar dust in 5×10^9 yr
and

(ii) SN shocks destroy dust in $< 1 \times 10^9$ yr

Interstellar dust must be formed in the ISM

Significant dust processing in the ISM also expected

Up to now a systematic variation in the UIR band is
observed in the halo of galaxies and elliptical galaxies

No systematic variation in the silicate feature (e.g.
crystallization) reported in the galaxy scale
(except for crystalline silicate in ULIRGs)

GEMS

(Glass with Embedded Metals & Sulfides)

Good interstellar dust analog
found in IDPs

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

Bradley et al. (1999)

IR Spectra of metal sulfides

Keller et al. (2002)

Metal sulfides have
 FeS band features in
 $20\text{--}30\mu\text{m}$

Fe_{1-x}S

Sulfide-rich IDPs

Metal sulfide features in celestial objects

C stars have a feature around 30 μm (MgS?)
~20-30 μm feature is seen in YSOs
and the Galactic Center

Depletion of sulfur

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

Depletion in dense clouds

Sulfur is not depleted in the ISM, but largely depleted
in dense clouds

Sulfur may be incorporated in GEMS in dense clouds

SPICA observations of dust formation and processing in the ISM

Spectroscopic observations of dense clouds in 10-200 μ m with medium spectral resolution to search for new dust features (e.g. sulfides)

and study grain formation and processing in the ISM

Gas abundance can also be derived in dense regions by spectroscopy of forbidden lines in MIR to FIR ([FeII]26, [SiII]35, [OI]63, 145, [CII]158, ...)

Same aperture size for different lines is important in deriving physical parameters (n_e , T, ..)

Medium spectral resolution with high sensitivity spectroscopy for $>20\mu$ m is required

Dust in galaxies

Spatially resolved spectra are indispensable to understand the properties of gas and dust in regions with different physical conditions in a galaxy

Key information of the physical conditions of each region can be derived from the study of gas

Dust circulation scenario in our Galaxy should be tested with the study of external galaxies that have a wide range of physical conditions

Dust survival and processing under harsh conditions, e.g., plasma environment in the halo, can only be studied with instruments of high sensitivity for diffuse emission

Dust in halo entrained by outflow

SPICA
Space Infrared Telescope for Cosmology and Astrophysics

FIR emission seen in the halo
well matched with X-ray
Dust must survive in the
outflow and reaches the halo
Energy source of the emission?

Origin and processing of UIR band carriers in galaxies

J.D. Smith et al. 2007;
Kaneda et al. 2008;
Onaka et al. 2008

7.7/11.3 μm band ratio is smaller in elliptical galaxies
Neutral carriers in elliptical galaxies
or carrier processing in a plasma environment?

UIR bands in the galaxy halo

H α (red) + AKARI 7 μ m

Engelbracht et al. 2006

UIR band detected in the halo region
extended more than H α
6.2/11.3 ratio smaller in the halo
Carbonaceous dust survival and
processing in the halo region need
further study

IR lines in galaxies

Negishi et al.

Neutral (PDR) gas
[OI]63, 145μm
[CII]158μm
[SII]35μm
[FeII]26, 35μm

HII regions
[OIII]52, 88μm
[NIII]57μm
[SIII]18, 33μm
[NeII]16, 36μm

Diffuse ionized gas
[NII]122, 204μm
[NeII]13μm
[CII]158μm
[SII]35μm, [FeII]

Contributions from each phase must be separated spatially
Same aperture size observations important to derive physical parameters

SPICA observations of nearby galaxies

Imaging spectroscopic observations of ~50 nearby galaxies in MIR to FIR to study physical conditions of individual regions, e.g, HII regions, galactic center, molecular clouds, and halo in galaxies and investigate dust formation, processing, and destruction in a galactic scale, including feedback from nuclear activities, effects of merging on material evolution, origin and evolution of carbonaceous and silicate grains

High spatial resolution and medium spectral resolution spectroscopic capability together with high sensitivity for diffuse emission in MIR and FIR (10 - 200 μ m) are crucial
Mapping capability is also important
